**PEPTOIDS AND METHODS FOR
ATTENUATING INFLAMMATORY
RESPONSE**

CROSS-REFERENCE TO RELATED
APPLICATIONS

This patent application claims the benefit of priority of U.S. Provisional Patent Application No. 62/699,296, filed on Jul. 17, 2018, which is incorporated herein by reference in its entirety.

BACKGROUND

Peptoids are peptidomimetics that attain invulnerability to proteolytic degradation through repositioning of the side-chain from the α -carbon to the amide nitrogen. This invulnerability to proteases, as well as other qualities such as diminished immunogenicity, enhanced cellular permeability, and capacity for intranasal administration, make peptoids immensely attractive as neurotherapeutic agents.

A peptoid mimic of $A\beta$'s KLVFF hydrophobic core, JPT1a, has the capacity to modulate $A\beta_{1-40}$ aggregation as

2

well as alter the morphology of $A\beta_{1-40}$ aggregates [US Pub. No. 2016/0376311, published Dec. 29, 2016 to Servoss et al.]. Amyloid- β ($A\beta$) has been the key therapeutic target for Alzheimer disease (AD)-related therapies, but more recent studies have recast $A\beta$ as one of several participants in the disease rather than its sole etiology. Recent clinical trials have shown that targeting AD-associated inflammation using an antagonist for the receptor for advanced glycation end products (RAGE) improves outcomes in patients with mild-to-moderate AD. As a result, there is a need for compositions that target RAGE-associated inflammation or antagonize RAGE.

BRIEF SUMMARY OF THE INVENTION

Disclosed herein are peptoids and methods for attenuating inflammatory responses, and more particularly RAGE-associated inflammatory responses. Methods for reversing or inhibiting RAGE expression in a cell presented with a stimulator of an innate immune response are provided. The methods comprise contacting the cell with an effective amount of a composition comprising a peptoid segment of formula

to reverse or inhibit RAGE expression in the cell. Each of R^1 , R^2 , R^3 , and R^4 may be independently selected from a branched or an unbranched, saturated or unsaturated, substituted or unsubstituted C_1 - C_{10} alkyl group, and each of A^1 , A^2 , A^3 , and A^4 may be independently selected from a branched or an unbranched, substituted or unsubstituted C_6 - C_{12} aryl or C_6 - C_{12} arylalkyl group. The stimulator of the innate immune response may be damage-associated molecular pattern (DAMP) or pathogen-associated molecular pattern (PAMP) molecules. Examples of stimulators include, without limitation, an advanced glycation endproduct (AGE), amyloid- β ($A\beta$), HMGB1, a S100, a nucleic acid, a bacterial endotoxin, and a virus.

The methods may also allow for accumulation of a cytokine in the cell or production of a cytokine by the cell to be reversed or inhibited. Suitably, the cytokine comprises IL-1 β , IL-6, IL-8, or a combination thereof.

Another aspect of the invention is a method for slowing or reversing progression of a RAGE-associated disease or disorder in a subject suffering therefrom. The method may comprise administering a therapeutically effective amount of a composition comprising a peptoid segment of formula

3

to the subject to slow or reverse progression of the RAGE-associated disease or disorder. Each of R¹, R², R³, and R⁴ may be independently selected from a branched or an unbranched, saturated or unsaturated, substituted or unsubstituted C₁-C₁₀ alkyl group, and each of A¹, A², A³, and A⁴ may be independently selected from a branched or an unbranched, substituted or unsubstituted C₆-C₁₂ aryl or C₆-C₁₂ arylalkyl group. The composition may be a pharmaceutical composition comprising the peptoid and a pharmaceutically acceptable carrier. The RAGE-associated disease or disorder may be Alzheimer's disease, arthritis, rheumatoid arthritis, Takayasu's arthritis, atherosclerosis, congestive heart failure, myocardial infarction, peripheral vascular disease, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, psoriasis, Parkinson's disease, multiple sclerosis, amyotrophic lateral sclerosis, or Creutzfeldt-Jakob disease.

With either of the methods described above, the peptoid may comprise a longer peptoid chain than the segment. In other embodiments, the peptoid comprises

Suitably, R¹ may comprise a terminally substituted C₁-C₆ aminoalkyl group. In certain embodiments, R¹ comprises 4-butylamine. Suitably, R², R³, and R⁴ may be independently selected from a branched or an unbranched, saturated or unsaturated, substituted or unsubstituted C₁-C₆ alkyl group. In some embodiments, each of R², R³, and R⁴ comprise the same group. Suitably, A¹, A², A³, and A⁴ may be independently selected from a branched or an unbranched, substituted or unsubstituted C₆-C₁₂ aryl or C₆-C₁₂ arylalkyl group.

BRIEF DESCRIPTION OF THE DRAWINGS

Non-limiting embodiments of the present invention will be described by way of example with reference to the accompanying figures, which are schematic and are not intended to be drawn to scale. In the figures, each identical or nearly identical component illustrated is typically represented by a single numeral. For purposes of clarity, not every component is labeled in every figure, nor is every component of each embodiment of the invention shown where illustration is not necessary to allow those of ordinary skill in the art to understand the invention.

FIG. 1 provides a schematic illustration for evaluating upregulation of RAGE and modulation of inflammatory response.

FIG. 2A shows that JPT1a modulates transmembrane RAGE expression in a dose-dependent manner.

FIGS. 2B-2D show that JPT1a attenuates pro-inflammatory cytokine expression of IL-1 β (FIG. 2B), IL-6 (FIG. 2C), and IL-8 (FIG. 2D).

FIG. 3 provides a schematic representation for evaluating reversal of RAGE.

FIG. 4A shows that JPT1a reduces transmembrane RAGE expression in previously-stimulated macrophages.

FIGS. 4B-4D show that JPT1a does not affect pro-inflammatory cytokine expression of IL-1 β (FIG. 4B), IL-6 (FIG. 4C), and IL-8 (FIG. 4D) in previously stimulated macrophages.

4

FIG. 5A shows that JPT1 modulates transmembrane RAGE expression in a dose-dependent manner.

FIGS. 5B-5D show that JPT1 attenuates pro-inflammatory cytokine expression of IL-1 β (FIG. 5B), IL-6 (FIG. 5C), and IL-8 (FIG. 5D).

FIGS. 6A-6C show that JPT1a is non-toxic to THP-1 macrophages as evaluated via XTT assay at 2 h (FIG. 6A), 4 h (FIG. 6B), and 24 h (FIG. 6C).

FIGS. 7A-7D show that JPT1a and JPT1 bind to RAGE selectively and with high affinity. FIGS. 7A-7B show the concentration of bound RAGE as a function of RAGE concentration (FIG. 7A) and E-cadherin concentration (FIG. 7B). FIGS. 7C-7D show Scatchard plots for JPT1a (FIG. 7C) and JPT1 (FIG. 7D).

FIGS. 8A-8B show that JPT1a binds to RAGE with low nanomolar affinity.

FIG. 9 demonstrates reduction in A β ₁₋₄₂ oligomer induced RAGE expression in macrophages treated with JPT1a.

DETAILED DESCRIPTION OF THE INVENTION

Disclosed herein are peptoids and methods for attenuating inflammatory responses, and more particularly RAGE-associated inflammatory responses. As demonstrated in the Examples that follow, co-incubation of a peptoid, such as JPT1a or JPT1, with the pro-inflammatory stimulus LPS significantly reduces RAGE upregulation in a dose dependent manner within a chronic inflammation model that utilizes THP-1 macrophages. In parallel, the peptoids disclosed herein also reduce the production of pro-inflammatory cytokines IL-1 β , IL-6, and IL-8. When paralleled by the ability of these peptoids to reverse RAGE expression, these results demonstrate the potential of peptoids, such as JPT1a or JPT1, as a dual-target therapy in AD, modulating both inflammation and A β aggregation. Moreover, RAGE is a promising therapeutic target in several pathologies, so a RAGE inhibitor, such as the peptoids described herein, yields new therapeutic options to a wide array of illnesses.

RAGE is a 35 kDa transmembrane receptor of the immunoglobulin super family and is implicated in diverse chronic inflammatory states. RAGE's name comes from its ability to bind advanced glycation end-products (AGE), which include glycoproteins, but RAGE is a multi-ligand pattern recognition receptor that binds and mediates the cellular response to a range of damage-associated molecular pattern molecules (DAMPs) including AGEs, A β , HMGB1, S100s, CD11b, RNA, and DNA. Additional RAGE ligands include, glycosylated sugars, heparan sulfate, high mobility group box 1 (HMGB1), lysophosphatidic acid (LPA), lipopolysaccharide (LPS), Mac-1, methylglyoxal-derived hydroimidazolone (MG-H1), phosphatidylserine, prions (i.e. prion diseases), quinolinic acid, and transthyretin. RAGE can also act

5

as an innate immune sensor of microbial pathogen-associated molecular pattern molecules (PAMPs) including bacterial endotoxin, respiratory viruses, and microbial DNA. RAGE is expressed at low levels under normal physiology,

but it is highly upregulated under chronic inflammation because of the accumulation of various RAGE ligands.

The interaction between RAGE and its ligands is believed to result in pro-inflammatory gene activation. Ligand binding results in RAGE signal activation of nuclear factor kappa B (NF- κ B), and RAGE, itself, is upregulated by NF- κ B. Due to an enhanced level of RAGE ligands in many chronic diseases and cancers, a positive feedback cycle can be established. Therefore, RAGE is believed to have a causative effect with inflammatory diseases, including, without limitation, Alzheimer's disease, arthritis, rheumatoid arthritis, Takayasu's arthritis, atherosclerosis, congestive

As used herein, a monomer of the peptoid is a single
15 (—NX—CH₂—CO—) group, where X is a side chain. Suitably, the peptoids are achiral or all the monomers have the same chirality. The peptoids shown may also be part of a larger peptoid. Such larger peptoids may include more than 8 monomers. For example the peptoid may comprise 10, 12,
20 15, 18, 20, 25, 30, 35 or any number of monomers therebetween. The additional monomers may be included on either end of the active peptoids described herein or may be included on only a single end.

In certain embodiments, the peptoid comprises an eight monomer peptoid having the general formula:

heart failure, myocardial infarction, peripheral vascular disease, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, psoriasis, Parkinson's disease, multiple sclerosis, amyotrophic lateral sclerosis, or Creutzfeldt-Jakob disease.

Peptoids are a class of peptidomimetics that are ideal candidates for use as therapeutic and detection agents due to their increased bioavailability (i.e. resistance to protease degradation) and low immune response. Peptoids have a backbone similar to peptides with the side chains attached to the amide nitrogen rather than the alpha-carbon. This small backbone change imparts protease resistance as well as an achiral backbone. However, inclusion of chiral side chains within the peptoid sequence allows for the formation of helical secondary structures. Specifically, peptoids containing chiral, aromatic side chains adopt a polyproline type-I like helix, which exhibits a ~6 Å helical pitch and 3 monomers per turn. Peptoid helices are extremely stable and do not denature in up to 8 M urea with temperatures up to 70° C. Peptoids allow for greater bioavailability than peptides since peptoid monomers are linked with an imide bond, which is resistant to proteolytic degradation, and the absence of hydrogen in amide groups in the backbone of the peptoids reduces compound polarity and improves membrane permeability. Use of peptoids may also reduce toxicity associated with peptide breakdown products. The peptoids described herein may be made and used using methods available to those skilled in the art. For example, see Zuckermann et al. Current Opinion in Molecular Therapeutics 11:299-307 (2009) and Ovadia et al. Bioorganic & Medicinal Chemistry 18:580-589 (2010) for information pertaining to the preparation and use of peptoids as therapeutics, the entire contents of which are incorporated herein in their entireties.

35 In some embodiments, the peptoid comprising eight residues is achiral.

In either of the formulas above, the R side chains of the peptoid are branched or unbranched, saturated or unsaturated, substituted or unsubstituted C₁-C₁₀ alkyl groups, and the A side chains of the peptoid comprise branched or an unbranched, substituted or unsubstituted C₆-C₁₂ aryl or C₆-C₁₂ arylalkyl groups.

R¹ may be selected from an unbranched, substituted or unsubstituted C₁-C₁₀, including without limitation a C₁-C₆ alkyl or a C₂-C₅ alkyl. If R¹ is substituted, the substitution is suitably a substituent comprising nitrogen such as an amine. R¹ may comprise a terminally substituted C₁-C₁₀ aminoalkyl group, including without limitation a terminally substituted C₁-C₆ aminoalkyl group or a terminally substituted C₂-C₅ aminoalkyl group. R¹ may have a positive charge or may be neutral. With the peptoid employed with the Examples, R¹ is 4-aminobutyl and the first monomer is N-(4-aminobutyl)glycine.

Each of R², R³, and R⁴ may independently be selected as an unsubstituted C₁-C₁₀ alkyl group, including without limitation an unsubstituted C₁-C₆ alkyl group or an unsubstituted C₂-C₅ alkyl group. In some embodiments, each of R², R³, and R⁴ comprise the same group. With the peptoid employed in the Examples, each of R², R³, and R⁴ may independently comprise a propyl group or a 1-methyl-prop-1-yl group.

Each of A¹, A², A³, and A⁴ may be independently selected from an unsubstituted C₆-C₁₂ aryl or C₆-C₁₂ arylalkyl group, including without limitation a C₆ aryl, a C₇-C₁₀ arylalkyl, or a C₇-C₈ aryl alkyl. In some embodiments, each of A¹, A², A³, and A⁴ comprise the same group. In some embodiments, each of A¹, A², A³, and A⁴ may independently comprise a

7

benzyl group or a 1-phenylethyl group. With the peptoid employed in the Examples, each of A¹, A², A³, and A⁴ comprise a —CH₂C₆H₅ group or —CH(CH₃)C₆H₅.

In some embodiments, the R and A groups are unbranched. In other embodiments the R and A groups are branched.

Table 1 shows the structure of exemplary peptoids JPT1a and JPT1, which may be made according to US Pat. Pub. 2016/0376311 and are used in the Examples. The Examples demonstrate that JPT1a is capable of reducing RAGE upregulation in a dose dependent manner and reduces the production of pro-inflammatory cytokines. The structure of JPT1a is shown in Table 1 and includes in the context of the general formulas above, R¹ of —(CH₂)₃NH₃⁺; R², R³, and R⁴ of —(CH₂)₂CH₃; and A¹, A², A³, and A⁴ is CH₂C₆H₅. The alkyl portion of each side chain (R or A side chains) may have a variable length, and the resulting peptoid is expected to attenuate RAGE-associated inflammatory responses.

8

aryl or arylalkyl. In other embodiments, one third or up to two thirds of the monomers have aryl or arylalkyl groups such that one or two out of every three side groups in the peptoid are aryl or arylalkyl groups. Suitably, the aryl or arylalkyl groups are —CH₂C₆H₅ or —CH(CH₃)C₆H₅ as shown in Table 1. Suitably, additional aryl or arylalkyl groups may be used such as a phenyl, phenylethyl, phenylpropyl, or phenylbutyl. The aryl portion of the groups may include between 6 and 30 carbons. The arylalkyl may be unbranched, substituted, or unsubstituted, and the alkyl portion may be saturated or unsaturated. Suitably, the aryl or arylalkyl groups are unsubstituted or substituted with N, S, or O.

The remaining side chains may be branched or unbranched, substituted or unsubstituted, saturated or unsaturated C₁-C₁₀ alkyl or C₄-C₁₀ cycloalkyl groups, such as those shown as R in the generic formula above. The R group is suitably a branched or unbranched, substituted or

TABLE 1

Structure and molecular weight of peptoids used herein.		
Name	Structure	MW (Da)
JPT1a		1032
JPT1		1130

In the peptoids described herein, at least two and as many as two-thirds of the monomers have side groups that are aryl or arylalkyl groups, such as those shown as A in the generic formula above. Suitably, the aryl or arylalkyl groups are arranged in the peptoid such that the peptoid has aryl or arylalkyl groups that are separated by two monomers. The peptoids may form a helical structure with three monomers per helical turn of the peptoid such that the aryl or arylalkyl groups are stacked on one side of the helix in the peptoids. In some embodiments, the aryl or arylalkyl groups are spaced such that every third monomer in the peptoid is an

unsubstituted, saturated or unsaturated, C₁-C₁₀ alkyl, C₄-C₁₀ aryl, C₄-C₁₀ arylalkyl, or C₄-C₁₀ cycloalkyl group. The R groups are independently selected from unbranched, substituted or unsubstituted, saturated or unsaturated, C₁-C₁₀ alkyl, aryl, heteroaryl, arylalkyl, cyclic, or heterocyclic groups. Suitably, the peptoid has at least eight monomers, similar to those shown in Table 1, in which R¹, R², R³, and R⁴ are independently selected from 4-aminobutyl, 3-amino-propyl, 2-aminoethyl, or aminomethyl, pentyl, butyl, propyl, ethyl, methyl. The R groups may be chiral or achiral as well.

The peptoids disclosed herein are capable of reversing or inhibiting RAGE expression in a cell presented with a stimulator of an innate immune response. Suitably, the peptoids are capable of reversing or inhibiting RAGE expression by at least 50% in a cell presented with a stimulator of the innate immune response, including without limitation by at least 60%, 70%, 75%, 80%, 85%, 90%, 93%, 95%, 97%, 98%, 99%, or more. Examples of stimulators of the innate immune response include DAMPs, e.g., AGEs, A β , HMGB1, S100s, and DNA, and PAMPs, e.g., bacterial endotoxin, viruses, and microbial DNA. As the Examples demonstrate, the peptoids disclosed herein are capable of reversing or inhibiting RAGE expression when macrophages are presented with the PAMP LPS and the DAMP A β .

The peptoids disclosed herein may also be capable of reversing or inhibiting cytokine accumulation in a cell presented with a stimulator of the innate immune response. Suitably, the peptoids are capable of reversing or inhibiting cytokine accumulation by at least 50% in a cell presented with a stimulator of the innate immune response, including without limitation by at least 60%, 70%, 75%, 80%, 85%, 90%, 93%, 95%, 97%, 98%, 99%, or more. The Examples also demonstrate the peptoids are capable of inhibiting the accumulation of pro-inflammatory cytokines, such as IL-1 β , IL-6, and IL-8, when macrophages are presented with the PAMP LPS.

The term “alkyl group” is intended to mean a group of atoms derived from an alkane by the removal of one hydrogen atom. Thus, the term includes straight or branched chain alkyl moieties including, for example, methyl, ethyl, propyl, isopropyl, butyl, tert-butyl, pentyl, hexyl, and the like. Preferred alkyl groups contain from 1 to about 14 carbon atoms (C₁₋₁₄ alkyl).

The term “aryl group” is intended to mean a group derived from an aromatic hydrocarbon by removal of a hydrogen from the aromatic system. Preferred aryl groups contain phenyl or substituted phenyl groups. Thus, the term “aryl” includes an aromatic carbocyclic radical having a single ring or two condensed rings. This term includes, for example, phenyl or naphthyl.

The term “heteroaryl” refers to aromatic ring systems of five or more atoms (e.g., five to ten atoms) of which at least one atom is selected from O, N, and S and includes, for example, furanyl, thiophenyl, pyridyl, indolyl, quinolyl, and the like.

“Substituted” means that one or more of the hydrogen atoms bonded to carbon atoms in the chain or ring have been replaced with other substituents. Suitable substituents include monovalent hydrocarbon groups including alkyl groups such as methyl groups and monovalent heterogeneous groups including alkoxy groups such as methoxy groups or amines. “Unsubstituted” means that the carbon chain or ring contains no other substituents other than carbon and hydrogen.

“Branched” means that the carbon chain is not simply a linear chain. “Unbranched” means that the carbon chain is a linear carbon chain.

“Saturated” means that the carbon chain or ring does not contain any double or triple bonds. “Unsaturated” means that the carbon chain or ring contains at least one double bond. An unsaturated carbon chain or ring may include more than one double bond.

The term “acyl” or “acetyl group” is intended to mean a group having the formula RCO—, wherein R is an alkyl group or an aryl group.

The term “alkenyl” refers to a straight or branched chain alkyl moiety having two or more carbon atoms (e.g., two to six carbon atoms, C₂₋₆ alkenyl) and having in addition one double bond of either E or Z stereochemistry where applicable. This term would include, for example, vinyl, 1-propenyl, 1- and 2-butenyl, 2-methyl-2-propenyl, etc.

The term “cycloalkyl” refers to a saturated alicyclic moiety having three or more carbon atoms (e.g., from three to six carbon atoms) and which may be optionally benzofused at any available position. This term includes, for example, cyclopropyl, cyclobutyl, cyclopentyl, cyclohexyl, indanyl, and tetrahydronaphthyl.

The term “heterocycloalkyl” refers to a saturated heterocyclic moiety having three or more carbon atoms (e.g., from three to six carbon atoms) and one or more heteroatom from the group N, O, S (or oxidized versions thereof) and which may be optionally benzofused at any available position. This term includes, for example, azetidiny, pyrrolidiny, tetrahydrofuranyl, piperidiny, indoliny, and tetrahydroquinoliny.

The term “cycloalkenyl” refers to an alicyclic moiety having three or more carbon atoms (e.g., from three to six carbon atoms) and having in addition one double bond. This term includes, for example, cyclopentenyl or cyclohexenyl.

The term “heterocycloalkenyl” refers to an alicyclic moiety having from three to six carbon atoms and one or more heteroatoms from the group N, O, S (or oxides thereof) and having in addition one double bond. This term includes, for example, dihydropyranly.

The term “arylalkyl” refers to an alkyl group as defined above substituted with one or more aryl group as defined above. Suitably, the arylalkyl group is an alkyl group substituted with one aryl group such as a phenylethyl or phenylmethyl group.

The term “halogen” means a halogen of the periodic table, such as fluorine, chlorine, bromine, or iodine.

The term “optionally substituted” means optionally substituted with one or more of the aforementioned groups (e.g., alkyl, aryl, heteroaryl, acyl, alkenyl, cycloalkyl, heterocycloalkyl, cycloalkenyl, heterocycloalkenyl, nitrogen, oxygen, sulfur, or halogen) at any available position or positions.

The compounds may be synthesized using conventional chemical technologies available to those skilled in the art.

Salts of the compounds described herein are also provided. Suitably, the salts are pharmaceutically acceptable. Acceptable salts of the compounds include, but are not limited to, hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate, bisulfate, phosphate, and acid phosphate.

The compounds may be used to make pharmaceutical compositions. Pharmaceutical compositions comprising the peptoids described above and a pharmaceutically acceptable carrier are provided. A pharmaceutically acceptable carrier is any carrier suitable for in vivo administration. Examples of pharmaceutically acceptable carriers suitable for use in the composition include, but are not limited to, water, buffered solutions, glucose solutions, and oil-based or bacterial culture fluids. Additional components of the compositions may suitably include, for example, excipients such as stabilizers, preservatives, diluents, emulsifiers, and lubricants. Examples of pharmaceutically acceptable carriers or diluents include stabilizers such as carbohydrates (e.g., sorbitol, mannitol, starch, sucrose, glucose, dextran), proteins such as albumin or casein, protein-containing agents such as bovine serum or skimmed milk and buffers (e.g., phosphate buffer). Especially when such stabilizers are

added to the compositions, the composition is suitable for freeze-drying or spray-drying. The composition may also be emulsified.

The peptoids provided herein may be used to make compositions capable of reversing or inhibiting RAGE expression both in vitro and in vivo and are capable of slowing or reversing the progression of RAGE-associated diseases or disorders in subjects suffering therefrom. In the methods, compositions comprising the peptoids described herein are administered to the subject in need of treatment. Suitably, the compositions are formulated and administered such that the peptoids are able to cross the blood-brain barrier. Suitably, the peptoids provided herein are able to treat or slow the progression of Alzheimer's disease, arthritis, rheumatoid arthritis, Takayasu's arthritis, atherosclerosis, congestive heart failure, myocardial infarction, peripheral vascular disease, diabetic neuropathy, diabetic nephropathy, diabetic retinopathy, psoriasis, Parkinson's disease, multiple sclerosis, amyotrophic lateral sclerosis, or Creutzfeldt-Jakob disease. Suitably, the subjects are mammals, more suitably, humans. Treatment of Alzheimer's disease includes, but is not limited to, prophylaxis of symptoms or indicators of the condition, reduction in disease severity or progression, or reversal, reduction, or slowing in disease progression as compared to an untreated subject.

The compositions described herein may be used to treat subjects in need of treatment for a RAGE-associated disease or disorder and may be used in combination with a second composition capable of inhibiting or slowing the progression of RAGE-associated disease or disorder. The two compositions used together to treat a subject may be administered simultaneously or concomitantly or one before the other in any order. The two compositions may be administered such that one is administered before the other with a difference in administration time of 1 hour, 2 hours, 4 hours, 8 hours, 12 hours, 16 hours, 20 hours, 1 day, 2 days, 4 days, 7 days, 2 weeks, 4 weeks, or more.

The compositions described herein may be administered by any means known to those skilled in the art, including, but not limited to, oral, topical, intranasal, intraperitoneal, parenteral, intravenous, intramuscular, subcutaneous, intrathecal, transcutaneous, nasopharyngeal, or via transmucosal absorption. Thus, the compositions may be formulated as an ingestible, injectable, intranasal, topical, or suppository formulation. The compositions may also be delivered within a liposomal or time-release vehicle. Suitably, the compositions are administered such that they are delivered or are able to cross the blood-brain barrier. Administration of the compositions to a subject appears to exhibit beneficial effects in a dose-dependent manner. Thus, within broad limits, administration of larger quantities of the compositions is expected to achieve increased beneficial biological effects than administration of a smaller amount. Moreover, efficacy is also contemplated at dosages below the level at which toxicity is seen.

It will be appreciated that the specific dosage administered in any given case will be adjusted in accordance with the composition or compositions being administered, the disease to be treated or inhibited, the condition of the subject, and other relevant medical factors that may modify the activity of the composition or the response of the subject, as is well known by those skilled in the art. For example, the specific dose for a particular subject depends on age, body weight, general state of health, diet, the timing and mode of administration, the rate of excretion, medicaments used in combination, and the severity of the particular disorder to which the therapy is applied. Dosages for a given patient can

be determined using conventional considerations, e.g., by customary comparison of the differential activities of the composition of the invention and of a known agent, such as by means of an appropriate conventional pharmacological or prophylactic protocol.

The maximal dosage for a subject is the highest dosage that does not cause undesirable or intolerable side effects. The number of variables in regard to an individual prophylactic or treatment regimen is large, and a considerable range of doses is expected. The route of administration will also impact the dosage requirements. It is anticipated that dosages of the composition will inhibit progression of the condition by at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, or 100% compared to pre-treatment symptoms or progression of the disease if left untreated. It is specifically contemplated that pharmaceutical preparations and compositions may palliate or alleviate symptoms of the disease without providing a cure, or, in some embodiments, may be used to stop progression of the disease or disorder and in some cases may even reverse progression.

Suitable effective dosage amounts for administering the compositions may be determined by those of skill in the art, but typically range from about 1 microgram to about 100,000 micrograms per kilogram of body weight weekly, although they are typically about 1,000 micrograms or less per kilogram of body weight weekly. In some embodiments, the effective dosage amount ranges from about 10 to about 10,000 micrograms per kilogram of body weight weekly. In another embodiment, the effective dosage amount ranges from about 50 to about 5,000 micrograms per kilogram of body weight weekly. In another embodiment, the effective dosage amount ranges from about 75 to about 1,000 micrograms per kilogram of body weight weekly. The effective dosage amounts described herein refer to total amounts administered, that is, if more than one composition is administered, the effective dosage amounts correspond to the total amount administered. The composition can be administered as a single dose or as divided doses. For example, the composition may be administered two or more times separated by 4 hours, 6 hours, 8 hours, 12 hours, a day, two days, three days, four days, one week, two weeks, or by three or more weeks.

An effective amount or a therapeutically effective amount as used herein means the amount of a composition that, when administered to a subject for treating a state, the disorder or condition is sufficient to affect a treatment (as defined above). The therapeutically effective amount will vary depending on the composition, formulation or composition, the disease and its severity, and the age, weight, physical condition, and responsiveness of the subject to be treated.

The present disclosure is not limited to the specific details of construction, arrangement of components, or method steps set forth herein. The compositions and methods disclosed herein are capable of being made, practiced, used, carried out, and/or formed in various ways that will be apparent to one of skill in the art in light of the disclosure that follows. The phraseology and terminology used herein is for the purpose of description only and should not be regarded as limiting to the scope of the claims. Ordinal indicators, such as first, second, and third, as used in the description and the claims to refer to various structures or method steps, are not meant to be construed to indicate any specific structures or steps, or any particular order or configuration to such structures or steps. All methods described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by

context. The use of any and all examples, or exemplary language (e.g., “such as”) provided herein, is intended merely to facilitate the disclosure and does not imply any limitation on the scope of the disclosure unless otherwise claimed. No language in the specification, and no structures shown in the drawings, should be construed as indicating that any non-claimed element is essential to the practice of the disclosed subject matter. The use herein of the terms “including,” “comprising,” or “having,” and variations thereof, is meant to encompass the elements listed thereafter and equivalents thereof, as well as additional elements. Embodiments recited as “including,” “comprising,” or “having” certain elements are also contemplated as “consisting essentially of” and “consisting of” those certain elements.

Recitation of ranges of values herein are merely intended to serve as a shorthand method of referring individually to each separate value falling within the range, unless otherwise indicated herein, and each separate value is incorporated into the specification as if it were individually recited herein. For example, if a concentration range is stated as 1% to 50%, it is intended that values such as 2% to 40%, 10% to 30%, or 1% to 3%, etc., are expressly enumerated in this specification. These are only examples of what is specifically intended, and all possible combinations of numerical values between and including the lowest value and the highest value enumerated are to be considered to be expressly stated in this disclosure. Use of the word “about” to describe a particular recited amount or range of amounts is meant to indicate that values very near to the recited amount are included in that amount, such as values that could or naturally would be accounted for due to manufacturing tolerances, instrument and human error in forming measurements, and the like. All percentages referring to amounts are by weight unless indicated otherwise.

No admission is made that any reference, including any non-patent or patent document cited in this specification, constitutes prior art. In particular, it will be understood that, unless otherwise stated, reference to any document herein does not constitute an admission that any of these documents form part of the common general knowledge in the art in the United States or in any other country. Any discussion of the references states what their authors assert, and the applicant reserves the right to challenge the accuracy and pertinence of any of the documents cited herein. All references cited herein are fully incorporated by reference, unless explicitly indicated otherwise. The present disclosure shall control in the event there are any disparities between any definitions and/or description found in the cited references.

The following examples are meant only to be illustrative and are not meant as limitations on the scope of the invention or of the appended claims.

Examples

JPT1a Prevents the Upregulation of RAGE and Modulates the Associated Inflammatory Response

Upregulation of RAGE and modulation of inflammatory response was evaluated as shown in FIG. 1. THP-1 monocytes were differentiated into macrophages through exposure to phorbol 12-myristate 13-acetate (PMA) for three days prior to experimentation 10. THP-1 monocytes differentiated in this manner have been shown to closely resemble the behavior and phenotype of primary human monocyte-derived macrophages. Upon differentiation, these cells were then incubated (3 days) with media containing JPT1a (50, 10, or 2 μ M) alone or JPT1a (50, 10, or 2 μ M) in the presence of low-dose (2 ng/mL) lipopolysaccharide (LPS) as a

chronic pro-inflammatory stimulus 11. Treatment with 2 ng/mL LPS alone served as a positive control, while treatment with an equivalent volume of buffer diluted into media served as the vehicle. Cellular supernatant was harvested on day 3 12; these samples were immediately centrifuged at 1200 rpm for 10 min at 25° C. to remove any cells or debris. The top 80% of this volume was subsequently removed and stored at -80° C. for later assessment of cytokines via ELISA. Cells were fixed and stained for RAGE, phalloidin (cytoplasmic marker), and DAPI (nuclear marker) 13. Each channel was imaged with a Zeiss LSM 510 META Confocal Scanning Laser Microscope using a plan-neofluar 40x/1.3 oil DIC immersion objective; three of these multi-channel images were obtained from each slide in each experiment 14. All multi-channel images were converted to TIFF file format via ImageJ64 software for quantitative image analysis using a custom subroutine written in Matlab™ software to obtain the average RAGE expression per volume of cells, and the data generated was assessed for statistical significance using GraphPad Prism 7.0 software 15.

As shown in FIG. 2A, THP-1 macrophages were treated with JPT1a alone (white) or in the presence of a chronic low-dose (2 ng/mL) of LPS (as a pro-inflammatory stimulus) (grey) for 3 days prior to fixation and staining for RAGE. Images acquired via confocal microscopy were analyzed via custom MATLAB™ subroutine to determine the average quantity of RAGE present within a given volume of cells. Results within each experiment are normalized to the positive control (2 ng/mL LPS alone), indicated by the dashed line at 1. Significance relative to positive control is indicated as ** $p < 0.01$. Error bars indicate SEM, $n = 4$. These results indicate that the upregulation in RAGE expression observed in the presence of the pro-inflammatory stimulus (LPS) is reduced in a dose-dependent and significant manner when cells are simultaneously exposed to JPT1a. In addition, treatment with JPT1a alone does not provoke significant response or upregulation in the expression of RAGE relative to the control.

As shown in FIGS. 2B-2D, THP-1 macrophages were treated with JPT1a alone (white) or in the presence of a chronic low-dose (2 ng/mL) of LPS (grey), for 3 days prior to supernatant harvest and storage. Examination of the supernatant via ELISA determined the concentrations of (FIG. 2B) IL-1 β , (FIG. 2C) IL-6, and (FIG. 2D) IL-8. Results are reported as a fraction of the positive control (2 ng/mL LPS alone) indicated by the dashed line at 1.0. ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$ vs positive control. Error bars indicate SEM, $n = 3-4$. These results indicate that treatment with JPT1a at 50 μ M significantly attenuates the LPS-induced production of cytokines IL-113, IL-6, and IL-8; treatment with JPT1a at 10 μ M also significantly reduces levels of LPS-induced IL-6 and IL-8. JPT1a Reverses the Upregulation of RAGE

Reversal of RAGE and modulation of inflammatory response was evaluated as shown in FIG. 3. THP-1 monocytes were differentiated as described above 20. Upon differentiation, these cells were then incubated (48 h) with media containing low-dose (2 ng/mL) LPS as a chronic pro-inflammatory stimulus 21. Following incubation, JPT1a or JPT1 was added for final concentrations of 25, 5, and 1 μ M 22, and cells were incubated an additional 24 h. Treatment with 2 ng/mL LPS alone served as a positive control, while treatment with an equivalent volume of buffer diluted into media served as the vehicle. Media was collected for later assessment of cytokines via ELISA as described above 23. Cells were fixed and stained for RAGE, phalloidin (cytoplasmic marker), and DAPI (nuclear marker) 24. Each

channel was imaged with a Zeiss LSM 510 META Confocal Scanning Laser Microscope using a plan-neofluar 40x/1.3 oil DIC immersion objective; three of these multi-channel images were obtained from each slide in each experiment. 25 All multi-channel images were converted to TIFF file format via ImageJ64 software for quantitative image analysis using a custom subroutine written in Matlab™ software to obtain the average RAGE expression per volume of cells, and the data generated was assessed for statistical significance using GraphPad Prism 7.0 software 26.

As shown in FIG. 4A, THP1 macrophages were treated with low-dose LPS at 2 ng/mL. After 48 hours, half of the supernatant was removed, treated with JPT1a (dashed-grey) at final concentrations of 25, 5, 1, and 0 μM (positive control), and then added back to respective samples. Following an additional 24 h incubation, cells were fixed, stained, and imaged via confocal microscopy. Images were analyzed via custom MATLAB™ subroutine to determine the average quantity of RAGE present within a given volume of cells. Results within each experiment are normalized to the positive control (2 ng/mL LPS alone), indicated by the dashed line at 1.0. *p<0.05, **p<0.01 vs positive control. Significance between treatments indicated as †p<0.05. Error bars indicate SEM, n=4. These results demonstrate a significant reversal in LPS-induced RAGE expression in macrophages upon treatment at 25 and 5 μM JPT1a.

JPT1a does not Affect Inflammatory Cytokine Production in Previously Stimulated Macrophages

As shown in FIGS. 4B-4D, THP1 macrophages were treated with low-dose LPS at 2 ng/mL. After 48 hours, half of the supernatant was removed, treated with JPT1a (dashed-grey) at final concentrations of 25, 5, 1, and 0 μM (positive control), and then added back to respective samples. Following an additional 24 h incubation, supernatant was harvested and examined for expression of IL-1β (FIG. 4B), IL-6 (FIG. 4C), and IL-8 (FIG. 4D) via ELISA. Results within each experiment are normalized to the positive control (2 ng/mL LPS alone), indicated by the dashed line at 1.0. ***p<0.001, ****p<0.0001 vs positive control. Error bars indicate SEM, n=2-3. These results indicate that JPT1a does not affect cytokine production of previously stimulated macrophages.

JPT1 Prevents the Upregulation of RAGE and Modulates the Associated Inflammatory Response

As shown in FIG. 5A, THP-1 macrophages were treated with JPT1 alone (white) or in the presence of a chronic low-dose (2 ng/mL) of LPS (grey), for 3 days prior to fixation and staining for RAGE as described above (FIG. 1). Images acquired via confocal microscopy were analyzed via custom MATLAB™ subroutine to determine the average quantity of RAGE present within a given volume of cells. Results within each experiment are normalized to the positive control (2 ng/mL LPS alone), indicated by the dashed line at 1.0. Error bars indicate SEM, n=2. These results indicate that the upregulation in RAGE expression observed in the presence of the pro-inflammatory stimulus (LPS) is reduced in a dose-dependent manner when cells are simultaneously exposed to JPT1. In addition, treatment with JPT1 alone does not provoke response or upregulation in the expression of RAGE relative to the control.

As shown in FIGS. 5B-5D, THP-1 macrophages were treated with JPT1 alone (white) or in the presence of a chronic low-dose (2 ng/mL) of LPS (grey), for 3 days prior to supernatant harvest and storage. Examination of the supernatant via ELISA determined the concentrations of (FIG. 5B) IL-1β, (FIG. 5C) IL-6, and (FIG. 5D) IL-8.

Results within each experiment are normalized to the positive control (2 ng/mL LPS alone), indicated by the dashed line at 1. * p<0.05, ** p<0.01, *** p<0.001, **** p<0.0001 vs positive control. Error bars indicate SEM; n=2-4. These results indicate that treatment with JPT1 at 50 μM significantly attenuates the LPS-induced production of cytokines IL-1β and IL-6;

JPT1a is Non-Toxic to THP-1 Macrophages

As shown in FIGS. 6A-6C, THP-1 macrophages remained untreated (grey) or were treated with JPT1a (white) at concentrations ranging from 1 to 50 μM. Toxicity was evaluated via XTT assay (Altman F P. Tetrazolium salts and formazans. Prog Histochem Cytochem. 1976; 9(3):1-56) at 2 h (FIG. 6A), 4 h (FIG. 6B), and 24 h (FIG. 6C) and it was determined that no change occurred in cells treated with JPT1a relative to cells treated with the vehicle alone. Results are reported as a fraction of cells treated with the vehicle alone, as indicated by the dashed line at 1. Error bars indicate SEM; n=2. These results indicate that JPT1a was non-toxic to macrophages even up to concentrations of 50 μM.

JPT1a and JPT1 Bind to RAGE Selectively

As shown in FIGS. 7A-7D, 96-well plates coated with 500 nM JPT1a were treated with concentrations of RAGE (FIG. 7A) or E-cadherin (FIG. 7B) ranging from 1 to 500 nM. Values are reported as the average concentration of bound protein determined from all experiments. Error bars indicate SEM, n=2-5. FIG. 7C shows a Scatchard plot for RAGE binding, which represents data generated from one trial; an average $K_d=51.8\pm 7.3$ nM was calculated from n=3. In FIG. 7D, 96-well plates coated with 500 nM JPT1 were treated with concentrations of RAGE ranging from 1 to 350 nM. This Scatchard plot for RAGE binding represents data generated from one trial that produced a $K_d=78.8$ nM, n=1. The concentrations of bound JPT1a-RAGE, shown in FIG. 7A, demonstrate a clear relationship of dose-dependence. In contrast, an absence of binding between JPT1a and E-cadherin, a cell adhesion molecule ubiquitously expressed on macrophages, is observed in FIG. 7B. The distinct difference in the binding relationships between the peptoid and these two molecules demonstrates the selectivity of these peptoids for RAGE. Furthermore, the binding between RAGE and both JPT1a and JPT1 is of high affinity, demonstrated by the nanomolar K_d values obtained from Scatchard plots in FIGS. 7C and 7D for this assay format.

JPT1a Binds to RAGE with Low Nanomolar Affinity

Definitive binding affinity of JPT1a for RAGE was determined from binding equilibrium attained in solution. As shown in FIGS. 8A-8B, 96-well plates coated with 500 nM JPT1a were treated with overnight incubations containing 20 nM RAGE and JPT1a in concentrations ranging from 0 nM to 1000 nM. Absorbance values were used to calculate relative $[RAGE]_{bound}$ and $[RAGE]_{free}$ via the Cheng-Prusoff method (Friguet B, Chaffotte A F, Djavadi-Ohanian L, Goldberg M E. Measurements of the true affinity constant in solution of antigen-antibody complexes by enzyme-linked immunosorbent assay. J Immunol Methods. 1985; 77(2): 305-319; Rath S, Stanley C M. An inhibition enzyme immunoassay for estimating relative antibody affinity and affinity heterogeneity. 1988; 106:245-249; Newton P, Harrison P, Clulow S. A Novel Method for Determination of the Affinity of Protein: Protein Interactions in Homogeneous Assays. 2008:674-682). FIG. 8A. Experimental values from four separate experiments (distinguished by circles, squares, diamonds, and triangles) were plotted via Scatchard plot,

17

which estimates a binding affinity of JPT1a for RAGE of 139.5 nM. Black dashed lines indicate 95% confidence interval, and gray dashed lines indicate 95% prediction interval, n=4. FIG. 8B. Data was also analyzed via plot of specific binding (one epitope) to yield K_d of 79.0 ± 28.4 nM. Dashed lines indicate 95% confidence interval, n=3. These experiments report a low nanomolar binding affinity of JPT1a for RAGE, demonstrating a high binding affinity that is within the range of other drug-like molecules.

JPT1a Reduces RAGE Upregulation in the Presence of Pre-Formed A β Oligomers.

A β_{1-42} oligomers were prepared at 15 μ M through the addition of 12 mM phosphate containing 5 μ M NaCl to DMSO-solubilized AP. After 15-minute incubation, oligomerization was halted and used to immediately prepare treatments of 10 nM A β_{1-42} oligomers alone (positive control) or in the presence of the peptoid at concentrations ranging from 1 μ M to 25 μ M. Treatments were applied to THP1 macrophages for 3 days prior to cell fixation and staining. Treatment with 10 nM A β_{1-42} oligomers alone served as a positive control, while treatment with an equivalent volume of buffer diluted into media served as the vehicle. Treatment with 15 μ M JPT1a ensured that JPT1a alone had no effect. Cells were fixed and stained for RAGE, phalloidin (cytoplasmic marker), and DAPI (nuclear marker). Each channel was imaged with a Zeiss LSM 510 META Confocal Scanning Laser Microscope using a plan-neofluar 40 \times /1.3 oil DIC immersion objective; three of these multi-channel images were obtained from each slide in each experiment. All multi-channel images were converted to TIFF file format via ImageJ64 software for quantitative image analysis using a custom subroutine written in MATLABTM software to obtain the average RAGE expression per volume of cells.

As shown in FIG. 9, THP1 macrophages were treated with 10 nM A β_{1-42} oligomers alone (positive control) or in the presence of JPT1a (25, 10, 5, or 1 μ M) (dashed). Treatment with an equivalent volume of buffer diluted into media served as the vehicle. Treatment with 25 μ M JPT1a in the presence of vehicle assessed the effect of the peptoid alone (black). Images were analyzed via custom MATLABTM subroutine to determine the average quantity of RAGE present within a given volume of cells. Data shown represent the average of a single experiment containing 3 replicates,

with all results reported as a fraction of the positive control, indicated by the dashed line at 1.0. These results indicate a dose-dependent reduction in A β_{1-42} oligomer induced RAGE expression in macrophages upon treatment with JPT1a. In addition, treatment with JPT1a alone does not provoke significant response or upregulation in the expression of RAGE.

We claim:

1. A method for reversing or inhibiting receptor for advanced glycation end products (RAGE) expression in a cell presented with a stimulator of an innate immune response, the method comprising contacting the cell pre-

18

sented with the stimulator of the innate immune response with an effective amount of a peptoid comprising a segment of formula

to reverse or inhibit RAGE expression in the cell, wherein R¹, R², R³, and R⁴ are independently selected from a branched or an unbranched, saturated or unsaturated, substituted or unsubstituted C₁-C₁₀ alkyl group, and A¹, A², A³, and A⁴ are independently selected from a branched or an unbranched, substituted or unsubstituted C₆-C₁₂ aryl or C₆-C₁₂ arylalkyl group.

2. The method of claim 1, wherein the effective amount of the peptoid to reverse or inhibit RAGE expression in the cell is an effective amount of the peptoid to reverse or inhibit accumulation of a cytokine in the cell or production of a cytokine by the cell.

3. The method of claim 2, wherein the cytokine comprises IL-1 β , IL-6, IL-8, or a combination thereof.

4. The method of claim 1, wherein the stimulator of the innate immune response is a damage-associated molecular pattern (DAMP) or a pathogen-associated molecular pattern molecules (PAMP).

5. The method of claim 4, wherein the stimulator of the innate immune response comprises a molecule selected from the group consisting of an advanced glycation end-product (AGE), amyloid- β (A β), HMGB1, a S100, a nucleic acid, a bacterial endotoxin, and a virus.

6. The method of claim 5, wherein the stimulator of the innate immune response comprises A β .

7. The method of claim 1, wherein the peptoid comprises a longer peptoid chain than the segment.

8. The method of claim 1, wherein the peptoid comprises

9. The method of claim 1, wherein R¹ comprises a terminally substituted C₁-C₆ aminoalkyl group.

10. The method of claim 1, wherein R¹ comprises 4-butylamine.

11. The method of claim 1, wherein R², R³, and R⁴ are independently selected from a branched or an unbranched, saturated or unsaturated, substituted or unsubstituted C₁-C₆ alkyl group.

12. The method of claim 11, wherein each of R², R³, and R⁴ comprise the same group.

13. The method of claim 11, wherein each of R², R³, and R⁴ comprise a propyl group or each of R², R³, and R⁴ comprise a 1-methyl-prop-1-yl group.

14. The method of claim 1, wherein each of A¹, A², A³, and A⁴ are independently selected from a branched or an unbranched, substituted or unsubstituted C₆ aryl or C₇-C₈ arylalkyl group.

15. The method of claim 14, wherein each of A¹, A², A³, and A⁴ comprise the same group.

16. The method of claim 14, wherein each of A¹, A², A³, and A⁴ comprise benzyl or each of A¹, A², A³, and A⁴ comprise 1-phenylethyl.

17. The method of claim 1, wherein the peptoid is JPT1a or JPT1.
